

# Algorithms and Applications

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Areas done in textbook:

- Sorting Algorithms
- Numerical Algorithms
- Image Processing
- Searching and Optimization

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Chapter 10

### Sorting Algorithms

- rearranging a list of numbers into increasing (strictly non-decreasing) order.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

### Potential Speedup

$(n \log n)$  optimal for any sequential sorting algorithm without using special properties of the numbers.

Best we can expect based upon a sequential sorting algorithm using  $n$  processors is

$$\text{Optimal parallel time complexity} = \frac{O(n \log n)}{n} = O(\log n)$$

Has been obtained but the constant hidden in the order notation extremely large.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

### Compare-and-Exchange Sorting Algorithms

#### Compare and Exchange

Form the basis of several, if not most, classical sequential sorting algorithms.

Two numbers, say  $A$  and  $B$ , are compared. If  $A > B$ ,  $A$  and  $B$  are exchanged, i.e.:

```
if (A > B) {
    temp = A;
    A = B;
    B = temp;
}
```

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

### Message-Passing Compare and Exchange

#### Version 1

$P_1$  sends  $A$  to  $P_2$ , which compares  $A$  and  $B$  and sends back  $B$  to  $P_1$  if  $A$  is larger than  $B$  (otherwise it sends back  $A$  to  $P_1$ ):

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Alternative Message Passing Method

Slide 7

### Version 2

For  $P_1$  to send  $A$  to  $P_2$  and  $P_2$  to send  $B$  to  $P_1$ . Then both processes perform compare operations.  $P_1$  keeps the larger of  $A$  and  $B$  and  $P_2$  keeps the smaller of  $A$  and  $B$ :

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Note on Precision of Duplicated Computations

Slide 8

Previous code assumes that the `if` condition,  $A > B$ , will return the same Boolean answer in both processors.

Different processors operating at different precision could conceivably produce **different answers** if real numbers are being compared.

This situation applies to anywhere computations are duplicated in different processors to reduce message passing, or to make the code SPMD.

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Data Partitioning

Slide 9

### (Version 1)

$p$  processors and  $n$  numbers.  $n/p$  numbers assigned to each processor:

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Merging Two Sublists — Version 2

Slide 10

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Bubble Sort

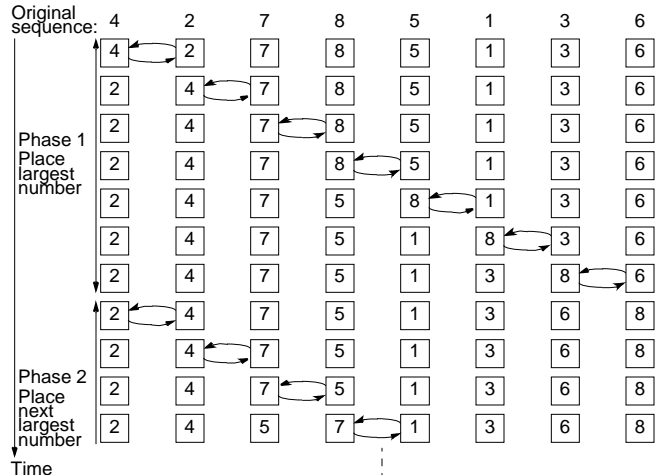

Slide 11

First, largest number moved to the end of list by a series of compares and exchanges, starting at the opposite end.

Actions repeated with subsequent numbers, stopping just before the previously positioned number.

In this way, the larger numbers move ("bubble") toward one end,

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Slide 12

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Time Complexity

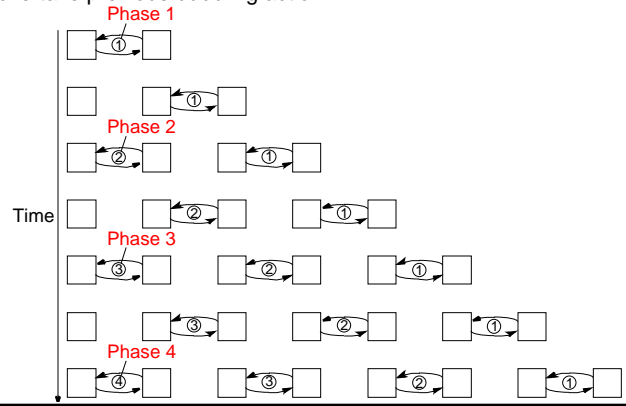

$$\text{Number of compare and exchange operations} = \sum_{i=1}^{n-1} i = \frac{n(n-1)}{2}$$

Indicates a time complexity of  $(n^2)$  given that a single compare-and-exchange operation has a constant complexity,  $(1)$ .

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Parallel Bubble Sort

Iteration could start before previous iteration finished if does not overtake previous bubbling action:

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Odd-Even (Transposition) Sort

Variation of bubble sort.

Operates in two alternating phases, *even* phase and *odd* phase.

### Even phase

Even-numbered processes exchange numbers with their right neighbor.

### Odd phase

Odd-numbered processes exchange numbers with their right neighbor.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Odd-Even Transposition Sort

Sorting eight numbers

Step	P <sub>0</sub>	P <sub>1</sub>	P <sub>2</sub>	P <sub>3</sub>	P <sub>4</sub>	P <sub>5</sub>	P <sub>6</sub>	P <sub>7</sub>
0	4	2	7	8	5	1	3	6
1	2	4	7	8	1	5	3	6
2	2	4	7	1	8	3	5	6
3	2	4	1	7	3	8	5	6
4	2	1	4	3	7	5	8	6
5	1	2	3	4	5	7	6	8
6	1	2	3	4	5	6	7	8
7	1	2	3	4	5	6	7	8

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Mergesort

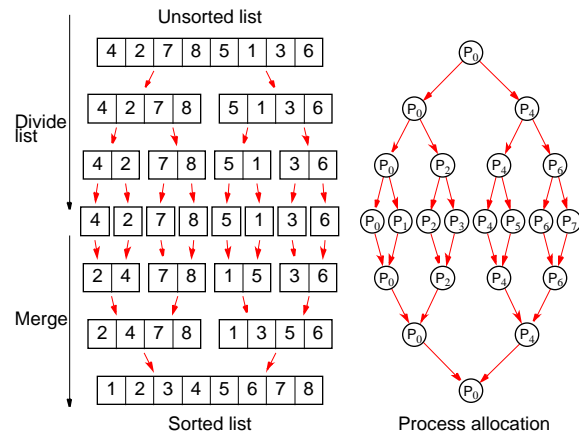

A classical sequential sorting algorithm using divide-and-conquer approach. Unsorted list first divided into half. Each half is again divided into two. Continued until individual numbers are obtained.

Then pairs of numbers combined (merged) into sorted list of two numbers. Pairs of these lists of four numbers are merged into sorted lists of eight numbers. This is continued until the one fully sorted list is obtained.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Parallelizing Mergesort

Using tree allocation of processes

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Analysis

### Sequential

Sequential time complexity is  $(n \log n)$ .

### Parallel

$2 \log n$  steps in the parallel version but each step may need to perform more than one basic operation, depending upon the number of numbers being processed - see text.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Quicksort

Very popular sequential sorting algorithm that performs well with an average sequential time complexity of  $(n \log n)$ .

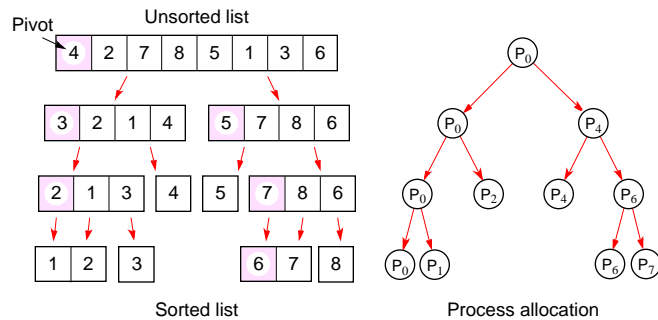

First list divided into two sublists. All the numbers in one sublist arranged to be smaller than all the numbers in the other sublist. Achieved by first selecting one number, called a *pivot*, against which every other number is compared. If the number is less than the pivot, it is placed in one sublist. Otherwise, it is placed in the other sublist.

Pivot could be any number in the list, but often the first number in the list is chosen. Pivot itself could be placed in one sublist, or the pivot could be separated and placed in its final position.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

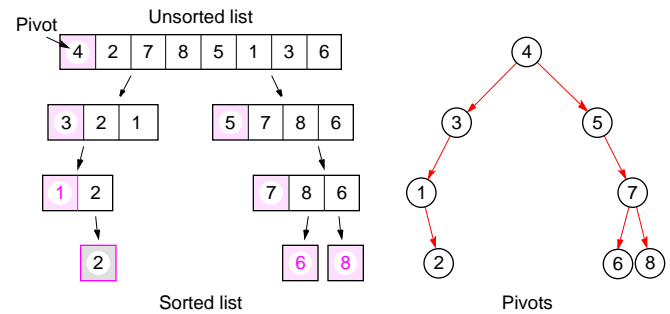

## Parallelizing Quicksort

Using tree allocation of processes

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

With the pivot being withheld in processes:

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Analysis

Fundamental problem with all tree constructions – initial division done by a single processor, which will seriously limit speed.

Tree in quicksort will not, in general, be perfectly balanced Pivot selection very important to make quicksort operate fast.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Work Pool Implementation of Quicksort

First, work pool holds initial unsorted list. Given to first processor which divides list into two parts. One part returned to work pool to be given to another processor, while the other part operated upon again.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Neither Mergesort nor Quicksort parallelize very well as the processor efficiency is low (see book for analysis).

Quicksort also can be very unbalanced. Can use load balancing techniques.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Batcher's Parallel Sorting Algorithms

- Odd-even Mergesort
- Bitonic Mergesort

Originally derived in terms of switching networks.

Both are well balanced and have parallel time complexity of  $O(\log^2 n)$  with  $n$  processors.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

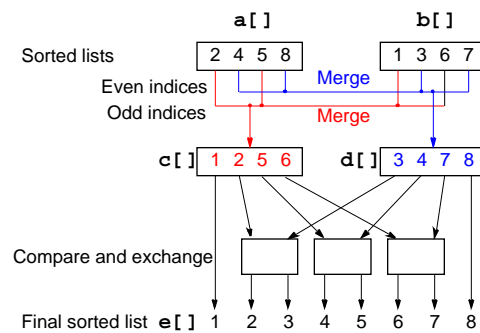

## Odd-Even Mergesort

### Odd-Even Merge Algorithm

Start with odd-even merge algorithm which will merge two *sorted* lists into one sorted list. Given two sorted lists  $a_1, a_2, a_3, \dots, a_n$  and  $b_1, b_2, b_3, \dots, b_n$  (where  $n$  is a power of 2)

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

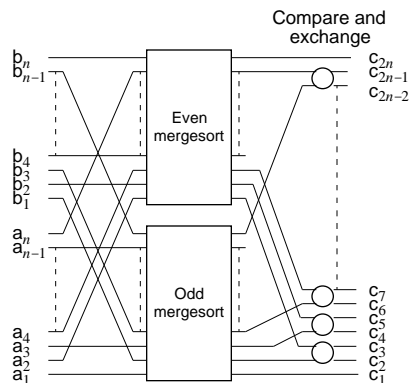

## Odd-Even Merging of Two Sorted Lists

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Odd-Even Mergesort

Apply odd-even merging recursively

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Bitonic Mergesort

### Bitonic Sequence

A **monotonic** increasing sequence is a sequence of increasing numbers.

A **bitonic sequence** has two sequences, one increasing and one decreasing. e.g.

$$a_0 < a_1 < a_2, a_3, \dots, a_{i-1} < a_i > a_{i+1}, \dots, a_{n-2} > a_{n-1}$$

for some value of  $i$  ( $0 < i < n$ ).

A sequence is also bitonic if the preceding can be achieved by shifting the numbers cyclically (left or right).

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Bitonic Sequences

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## “Special” Characteristic of Bitonic Sequences

If we perform a compare-and-exchange operation on  $a_i$  with  $a_{i+n/2}$  for all  $i$ , where there are  $n$  numbers in the sequence, get **TWO** bitonic sequences, where the numbers in one sequence are **all less than the numbers in the other sequence**.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Example - Creating two bitonic sequences from one bitonic sequence

Starting with the bitonic sequence

3, 5, 8, 9, 7, 4, 2, 1

we get:

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Sorting a bitonic sequence

Compare-and-exchange moves smaller numbers of each pair to left and larger numbers of pair to right. **Given a bitonic sequence**, recursively performing operations will sort the list.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Sorting

To sort an **unordered sequence**, sequences are merged into larger bitonic sequences, starting with pairs of adjacent numbers.

By a compare-and-exchange operation, pairs of adjacent numbers are formed into increasing sequences and decreasing sequences, pairs of which form a bitonic sequence of twice the size of each of the original sequences.

By repeating this process, bitonic sequences of larger and larger lengths are obtained.

In the final step, a single bitonic sequence is sorted into a single increasing sequence.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Bitonic Mergesort

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Bitonic Mergesort on Eight Numbers

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Phases

The six steps (for eight numbers) are divided into three phases:

Phase 1 (Step 1) Convert pairs of numbers into increasing/decreasing sequences and hence into 4-bit bitonic sequences.

Phase 2 (Steps 2/3) Split each 4-bit bitonic sequence into two 2-bit bitonic sequences, higher sequences at center.

Sort each 4-bit bitonic sequence increasing/decreasing sequences and merge into 8-bit bitonic sequence.

Phase 3 (Steps 4/5/6) Sort 8-bit bitonic sequence.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Number of Steps

In general, with  $n = 2^k$ , there are  $k$  phases, each of 1, 2, 3, ...,  $k$  steps. Hence the total number of steps is given by

$$\text{Steps} = \sum_{i=1}^k i = \frac{k(k+1)}{2} = \frac{\log n (\log n + 1)}{2} = (\log^2 n)$$

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Sorting Conclusions so far

Computational time complexity using  $n$  processors

- Odd-even transposition sort-  $O(n)$
- Parallel mergesort -  $O(n)$  but unbalanced processor load and communication
- Parallel quicksort -  $O(n)$  but unbalanced processor load, and communication can generate to  $O(n^2)$
- Odd-even Mergesort and Bitonic Mergesort  $O(\log^2 n)$

Bitonic mergesort has been a popular choice for a parallel sorting.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Sorting on Specific Networks

Algorithms can take advantage of the underlying interconnection network of the parallel computer.

Two network structures have received specific attention: the **mesh** and **hypercube** because parallel computers have been built with these networks.

Of less interest nowadays because underlying architecture often hidden from user - We will describe a couple of representative algorithms.

MPI does provide features for mapping algorithms onto meshes, and one can always use a mesh or hypercube algorithm even if the underlying architecture is not the same.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Mesh - Two-Dimensional Sorting

The layout of a sorted sequence on a mesh could be row by row or **snake-like**. Snake-like:

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Shearsort

Alternate row and column sorting until list fully sorted. Row sorting alternative directions to get snake-like sorting:

(a) Original placement of numbers

(b) Phase 1 — Row sort

(c) Phase 2 — Column sort

(d) Phase 3 — Row sort

(e) Phase 4 — Column sort

(f) Final phase — Row sort

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Shearsort

Requires  $\sqrt{n}(\log n + 1)$  steps for  $n$  numbers on a  $\sqrt{n} \times \sqrt{n}$  mesh.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Using Transposition

Causes the elements in each column to be in positions in a row.  
Can be placed between the row operations and column operations:

(a) Operations between elements in rows

(b) Transpose operation

(c) Operations between elements in rows (originally columns)

Transposition can be achieved with  $\sqrt{n}(\sqrt{n} - 1)$  communications ( $n$ ). An *all-to-all* routine could reduce this.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Hypercube

### Quicksort

Hypercube network has structural characteristics that offer scope for implementing efficient divide-and-conquer sorting algorithms, such as quicksort.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Complete List Placed in One Processor

Suppose a list of  $n$  numbers placed on one node of a  $d$ -dimensional hypercube. List can be divided into two parts according to the quicksort algorithm by using a pivot determined by the processor, with one part sent to the adjacent node in the highest dimension. Then the two nodes can repeat the process.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

### Example

3-dimensional hypercube with the numbers originally in node 000:

	Node	Node	
1st step:	000	001	(numbers greater than a pivot, say $p_1$ )
2nd step:	000	010	(numbers greater than a pivot, say $p_2$ )
	001	011	(numbers greater than a pivot, say $p_3$ )
3rd step:	000	100	(numbers greater than a pivot, say $p_4$ )
	001	101	(numbers greater than a pivot, say $p_5$ )
	010	110	(numbers greater than a pivot, say $p_6$ )
	011	111	(numbers greater than a pivot, say $p_7$ )

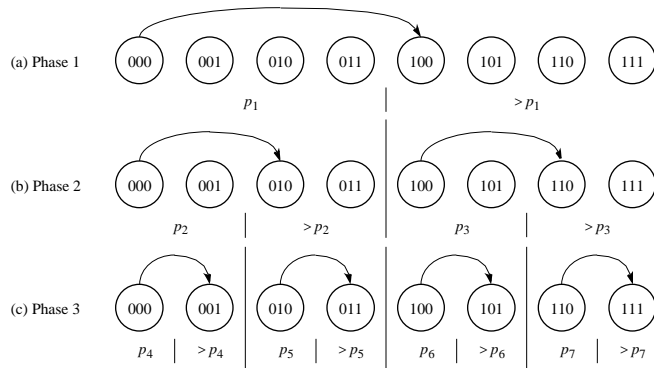

Finally, the parts sorted using a sequential algorithm, all in parallel. If required, sorted parts can be returned to one processor in a sequence that allows processor to concatenate the sorted lists to create the final sorted list.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Hypercube quicksort algorithm when the numbers are originally in node 000

Slide 49

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

There are other hypercube quicksort algorithms - see textbook.

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Other Sorting Algorithms

Slide 51

We began by giving the lower bound for the time complexity of a sequential sorting algorithm based upon comparisons as  $O(n \log n)$ . Consequently, the time complexity of a parallel sorting algorithm based upon comparisons is  $O((\log n)/p)$  with  $p$  processors or  $O(\log n)$  with  $n$  processors.

There are sorting algorithms that can achieve better than  $O(n \log n)$  sequential time complexity and are very attractive candidates for parallelization but they often assume special properties of the numbers being sorted.

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

First, let us look at one sorting algorithm, **rank sort**, that does not achieve a sequential time of  $O(n \log n)$ , but can be parallelized easily, and leads us onto linear sequential time algorithms which can be parallelized to achieve  $O(\log n)$  parallel time and are attractive algorithms for clusters.

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Rank Sort

Slide 53

The number of numbers that are smaller than each selected number is counted. This count provides the position of selected number in sorted list; that is, its "rank."

First  $a[0]$  is read and compared with each of the other numbers,  $a[1] \dots a[n-1]$ , recording the number of numbers less than  $a[0]$ . Suppose this number is  $x$ . This is the index of the location in the final sorted list. The number  $a[0]$  is copied into the final sorted list  $b[0] \dots b[n-1]$ , at location  $b[x]$ . Actions repeated with the other numbers.

Overall sequential sorting time complexity of  $(n^2)$  (not exactly a good sequential sorting algorithm!).

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Sequential Code

Slide 54

```
for (i = 0; i < n; i++) {           /* for each number */
    x = 0;
    for (j = 0; j < n; j++) /* count number less than it */
        if (a[i] > a[j]) x++;
    b[x] = a[i];                 /* copy number into correct place */
}
```

This code will fail if duplicates exist in the sequence of numbers. Easy to fix. (How?)

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Parallel Code Using $n$ Processors

One processor allocated to each number. Finds final index in  $(n)$  steps. With all processors operating in parallel, parallel time complexity  $(n)$ .

In `forall` notation, the code would look like

```
forall (i = 0; i < n; i++) { /* for each no in parallel */
  x = 0;
  for (j = 0; j < n; j++) /* count number less than it */
    if (a[i] > a[j]) x++;
  b[x] = a[i]; /* copy no into correct place */
}
```

Parallel time complexity,  $(n)$ , as good as any sorting algorithm so far. Can do even better if we have more processors.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Using $n^2$ Processors

Comparing one number with the other numbers in list using multiple processors:

$n - 1$  processors used to find rank of one number. With  $n$  numbers,  $(n - 1)n$  processors or (almost)  $n^2$  processors needed. Incrementing the counter done sequentially and requires maximum of  $n$  steps. Total number of steps is by  $1 + n$ .

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Reduction in Number of Steps

Tree to reduce number of steps involved in incrementing counter:

$(\log n)$  algorithm with  $n^2$  processors.  
Processor efficiency relatively low.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Parallel Rank Sort Conclusions

Easy to do as each number can be considered in isolation.

Rank sort can sort in:

$(n)$  with  $n$  processors

or

$(\log n)$  using  $n^2$  processors.

In practical applications, using  $n^2$  processors prohibitive.

Theoretically possible to reduce time complexity to  $(1)$  by considering all increment operations as happening in parallel since they are independent of each other.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Message Passing Parallel Rank Sort Master-Slave Approach

Requires shared access to list of numbers. Master process responds to request for numbers from slaves. Algorithm better for shared memory

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Counting Sort

If the numbers to be sorted are integers, there is a way of coding the rank sort algorithm to reduce the sequential time complexity from  $O(n^2)$  to  $O(n)$ , called as *Counting Sort*.

Counting sort is naturally a **stable sorting algorithm** (that is, it will place identical numbers in the same order as in the original sequence).

As in the rank sort code suppose the unsorted numbers stored in an array `a[]` and final sorted sequence is stored in array `b[]`. Algorithm uses an additional array, say `c[]`, having one element for each possible value of the numbers. Suppose the range of integers is from 1 to  $m$ . The array has element `c[1]` through `c[m]` inclusive. Now, let us working through the algorithm in stages.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

First,  $c[]$  will be used to hold the histogram of the sequence, that is, the number of each number. This can be computed in  $O(m)$  time with code such as:

```
for (i = 1; i <= m; i++)
    c[i] = 0;
for (i = 1; i <= m; i++)
    c[a[i]]++;
```

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Next stage: The number of numbers less than each number found by performing a prefix sum operation on array  $c[]$ .

In the prefix sum calculation, given a list of numbers,  $x_0, \dots, x_{n-1}$ , all the partial summations (i.e.,  $x_0$ ;  $x_0 + x_1$ ;  $x_0 + x_1 + x_2$ ;  $x_0 + x_1 + x_2 + x_3$ ; ...) are computed.

Here, the prefix sum is computed using the histogram originally held in  $c[]$  in  $O(m)$  time as described below:

```
for (i = 2; i <= m; i++)
    c[i] = c[i] + c[i-1];
```

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Final stage: The numbers are placed in the sorted order in  $O(n)$  time as described below:

```
for (i = n; i >= 1; i--) {
    b[c[a[i]]] = a[i]
    c[a[i]]--;      /* done to ensure stable sorting */
}
```

Complete code has  $O(n + m)$  sequential time complexity. If  $m$  is linearly related to  $n$  as it is in some applications, the code has  $O(n)$  sequential time complexity.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Parallelizing counting sort can use the parallel version of the prefix sum calculation which requires  $O(\log n)$  time with  $n - 1$  processors. The final sorting stage can be achieved in  $O(n/p)$  time with  $p$  processors or  $O(1)$  with  $n$  processors by simply having the body of the loop done by different processors.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Counting sort

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Radix Sort

Assumes numbers to sort are represented in a positional digit representation such as binary and decimal numbers. The digits represent values and position of each digit indicates their relative weighting.

Radix sort starts at the least significant digit and sorts the numbers according to their least significant digits. The sequence is then sorted according to the next least significant digit and so on until the most significant digit, after which the sequence is sorted. For this to work, it is necessary that the order of numbers with the same digit is maintained, that is, one must use a stable sorting algorithm.

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Radix sort using decimal digits

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

## Radix sort using binary digits

Barry Wilkinson 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Radix sort can be parallelized by using a parallel sorting algorithm in each phase of sorting on bits or groups of bits.

Already mentioned parallelized counting sort using prefix sum calculation, which leads to  $O(\log n)$  time with  $n - 1$  processors and constant  $b$  and  $r$ .

## Example of parallelizing radix sort sorting on binary digits

Can use prefix-sum calculation for positioning each number at each stage. When prefix sum calculation applied to a column of bits, it gives number of 1's up to each digit position because all the digits can only be 0 or 1 and the prefix calculation will simply add the number of 1's. A second prefix calculation can also give the number of 0's up to each digit position by performing the prefix calculation on the digits inverted ( *diminished prefix sum* ). In the case of the digit of the number considered being a 0, the diminished prefix sum calculation provides the new position for the number. In the case of the digit being a 1, the result of normal prefix sum calculation plus the largest diminished prefix calculation gives the final position for the number.

## Sample Sort

Sample sort is an old idea (pre1970) as are many basic sorting ideas. Has been discussed in the context of quicksort and bucket sort.

In the context of quicksort, sample sort takes a sample of  $s$  numbers from the sequence of  $n$  numbers. The median of this sample is used as the first pivot to divide the sequence into two parts as required as the first step by the quicksort algorithm rather than the usual first number in the list.

In context of bucket sort, objective of sample sort is to divide the ranges so that each bucket will have approximately the same number of numbers.

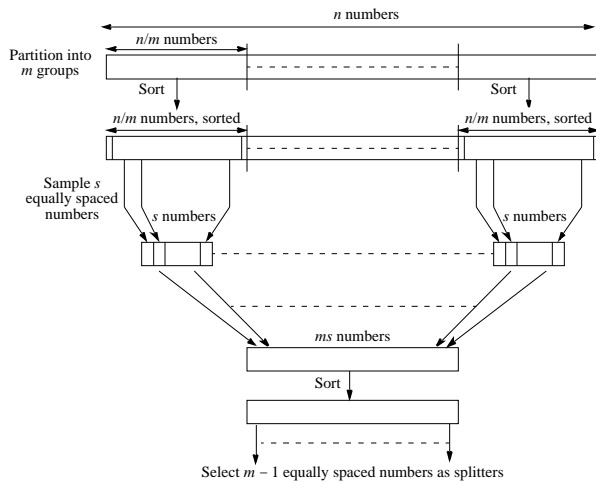

Does this by using a sampling scheme which picks out numbers from the sequence of  $n$  numbers as splitters which define the range of numbers for each bucket. If there are  $m$  buckets,  $m - 1$  splitters are needed.

Can be found by the following method. The numbers to be sorted are first divided into  $n/m$  groups. Each group is sorted and a sample of  $s$  equally spaced numbers are chosen from each group. This creates  $ms$  samples in total which are then sorted and  $m - 1$  equally spaced numbers selected as splitters.

### Implementing Sorting Algorithms on Clusters

Slide 74

Factors for efficient implementation on clusters include using broadcast and other collective operations such as gather, scatter, and reduce provided in message-passing software such as MPI rather than non-uniform communication patterns that require point-to-point communication, because collective operations expected to be implemented efficiently.

Other factors include that the distributed memory of a cluster does not favor algorithms requiring access to widely separated numbers. Algorithms that require only local operations are better, although all sorting algorithms finally have to move numbers in the worst case from one end of the sequence to the other somehow.

Barry Wilkinson. 2003. This material is for sole and exclusive use of students enrolled at Western Carolina University. It is not to be sold, reproduced, or generally distributed.

Processors always have cache memory and it is better to have an algorithm that operate upon a block of numbers that can be placed in the cache. In that respect, one will need to know the size and organization of the cache, and this has to become part of the algorithm as parameters.

Finally with the advent of clusters of SMP processors (SMP clusters), algorithms need to take into account that the groups of processors in each SMP system may operate in the shared memory mode where the shared memory is only within each SMP system, whereas each system may communicate with other SMP systems in the cluster in a message-passing mode. Again to take this into account requires parameters such as number of processors within each SMP system and size of the memory in each SMP system.
